

Regional Income Disparities, Distributional Convergence, and Spatial Effects

Evidence from Indonesian Regions 2010-2017

Prepared for the QuaRCS lab meeting on September 3rd 2020

[slides available at: <https://project2019e.netlify.app>]

Motivation:

- there is limited research about decentralization in Indonesia that has provided a conclusive answer on the regional income disparity dynamics.
- Scarce academic literature on convergence at the district level in Indonesia.

Research Question:

- **To what extent the role of space affects the convergence dynamics across Indonesian regions?**

Methods:

- Classical convergence framework (Barro and Sala-i-Martin 1992) and Distributional convergence framework (Quah 1996; Hyndman et. al 1996)
- Spatial autocorrelation (Moran's I and differential Moran's I)
- Getis Filter (Getis 1995)

Main Results

1. **Significant Spatial Autocorrelation** at the district level.

2. **Distributional Convergence**

- For provinces, there are 4 convergence clubs.
- For districts high mobility in the upper tail of the distribution.

3. **Filtered data**

- High mobility on the filtered distribution.
- Faster convergence speed for filtered data.

4. **Spatial effects**

- Spatial effects are reducing the speed convergence of income at the district level.

5. **Policy Implication**

- Increasing the effectiveness of local government's policies and coordination among regions.

Outline of this presentation

1. **Introduction and Data**

- Does decentralization promote regional development?
- A newly constructed data-set

2. **Spatial autocorrelation**

- Standard Moran's I
- Differential Moran's I

3. **Spatial Filtering Perspectives**

- Distributional Dynamic Framework
- Getis Spatial Filter

4. **Income dynamic transition across districts and provinces**

5. **The filtered data and spatial effects**

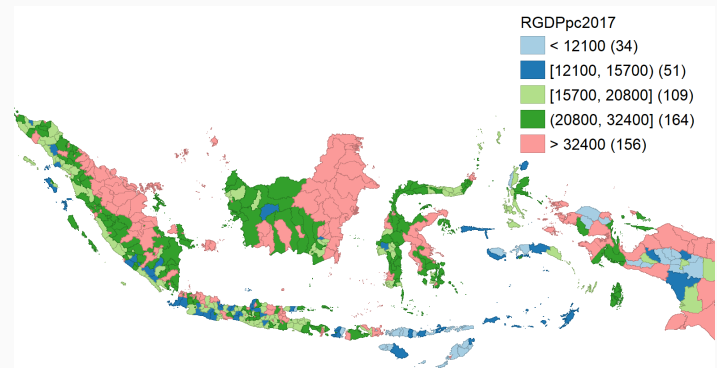

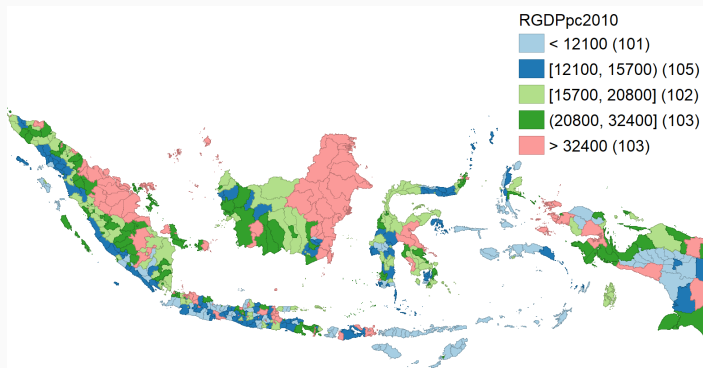

6. **Concluding Remarks**

(1) Data

- The centroid coordinates of the capital cities of the districts.

- A balanced dataset (districts interpolation). Income per capita for 34 provinces and 514 districts over the 2010-2017 period.

(1) Introduction:

Decentralization to promote regional growth

- After the implementation of decentralization in 2000, the number of provinces and districts (cities and regencies) increased significantly.
- Local governments are granted a greater political autonomy and substantial responsibilities for administration and public services provision.

(2) Spatial Autocorrelation :

Moran's I and Differential Moran's I

$$I = \frac{\sum_i \sum_j w_{ij} z_i \cdot z_j}{\sum_i z_i^2} = \frac{\sum_i (z_i \times \sum_j w_{ij} z_j)}{\sum_i z_i^2}.$$

- It captures the relationship of a variable in one location with the spatially weighted average of values at neighboring locations.
- The differential Moran's I is conducted to evaluate the robustness.

Positive spatial
autocorrelation

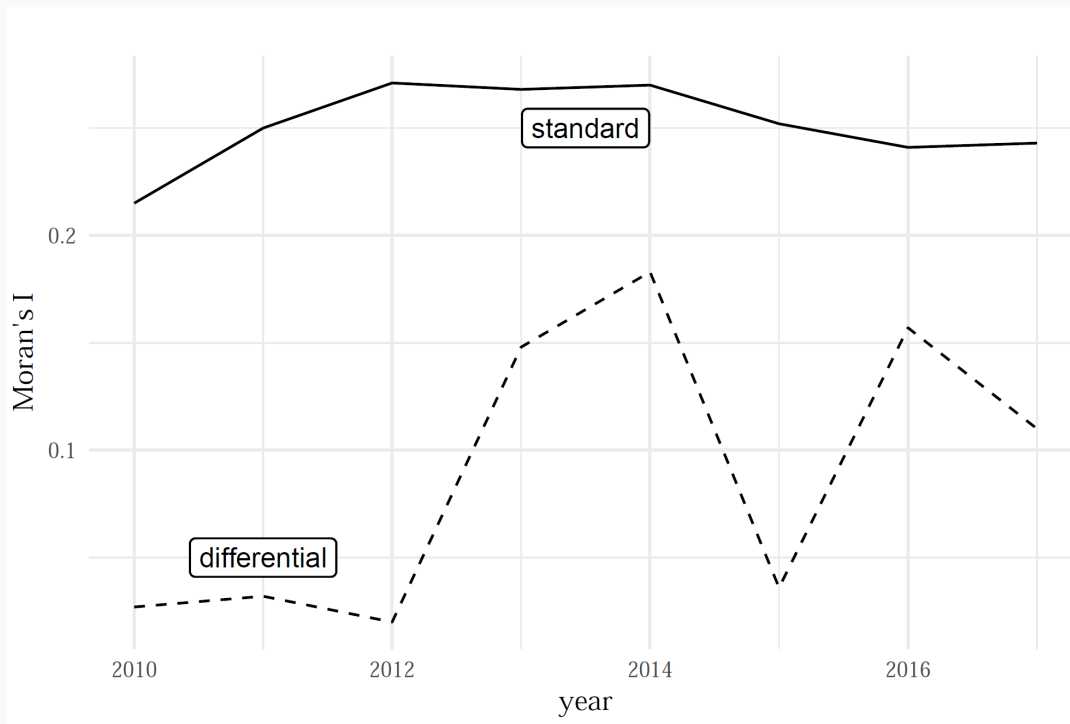

No spatial
autocorrelation

Negative spatial
autocorrelation

Spatial Autocorrelation Moran's I

- For provincial data the Moran's I statistic was **not statistically different from 0** for all years.
- At the district level there are **Strong signs of positive spatial autocorrelation**
- The Moran's I is significant **for all years** from 2010-2017 and the differential Moran's I is significant from 2013

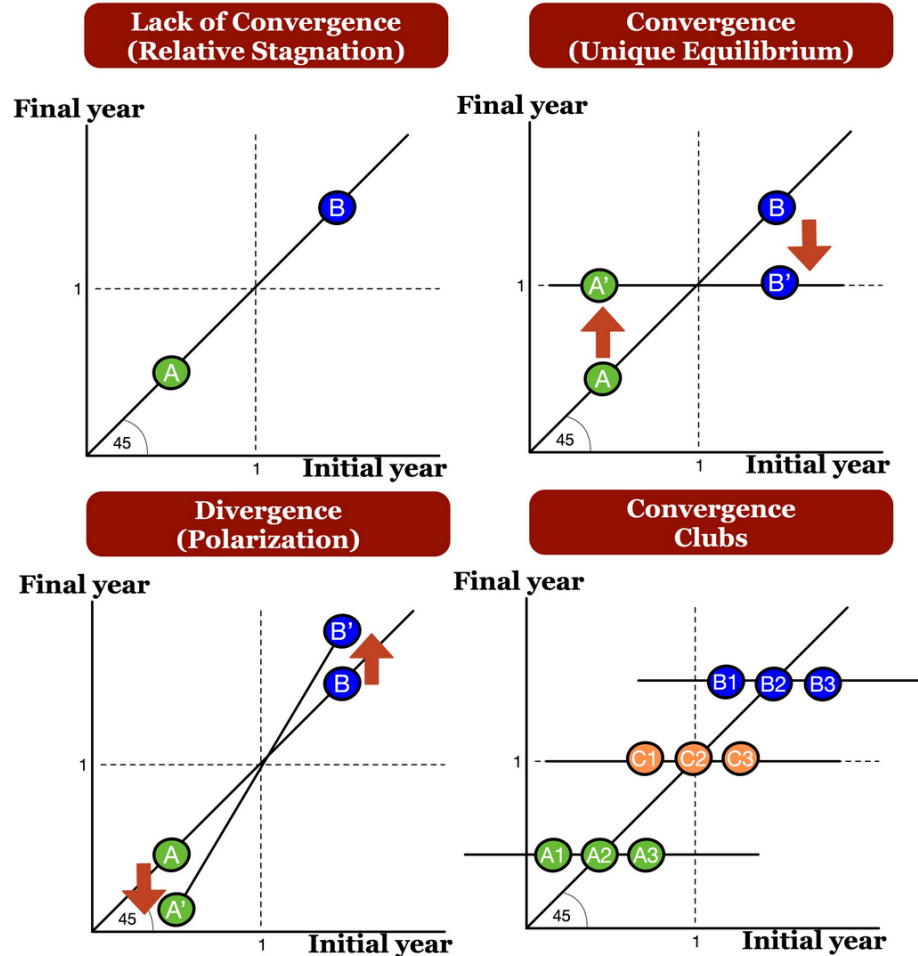

(3) Spatial Filtering Perspective

$$x_i^* = \frac{xi(W_i)}{(n-1)G_i(d_m)}$$

- **A spatial filtering of the data can help us to avoid misguided interpretation.**
- Instead of using spatial regressions we can remove the spatial component of socio-economic variables and use the filtered data in regular regressions.

(3) Distribution Dynamics Framework

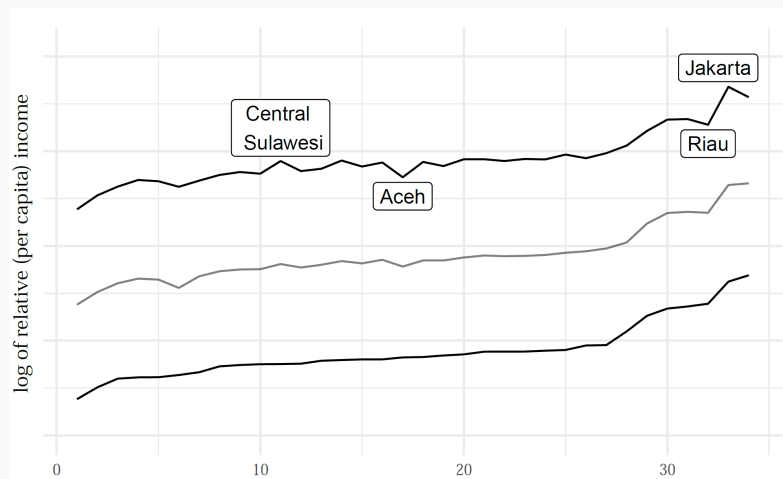

Intra-distribution dynamics

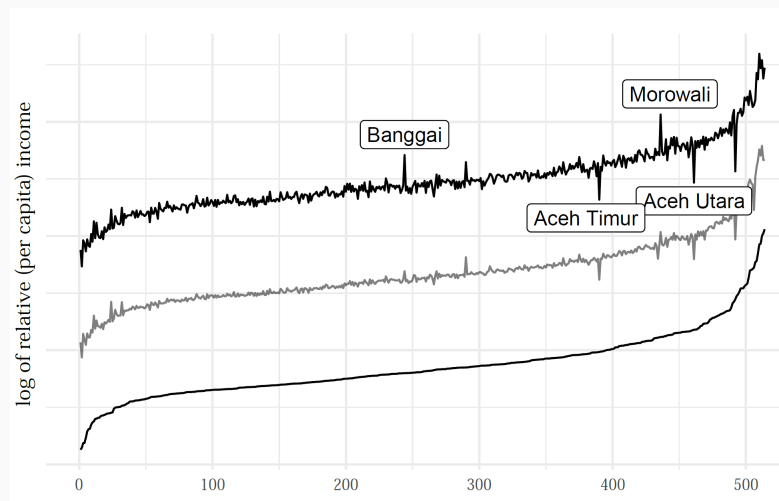

Is the income ranking changing over time?

- Each curve refers to the income levels at a given point in time 2010, 2013 and 2017.
- The lowest curve shows the cross-section of regions in 2010 in increasing order (income ranking from the lowest to the highest)

Provinces

Districts

(4) Income dynamics for districts

- Low mobility in the bottom of the distribution, the relatively poor remain relatively poor...
- High mobility in the upper tail of the distribution

(4) Income dynamics - provinces

Since Spatial autocorrelation is not significant for provinces just distributional and classical convergence analysis are reported.

There are at least 2 convergence clubs, two in the upper tail and 2 in the middle of the distribution

(5) Filtered income dynamics

- Distributional convergence and clusters for the **filtered income variable**
- The regions whith income over 20 times the average income un time t had income of just over 15 in time $t+5$

(5) Classical convergence results

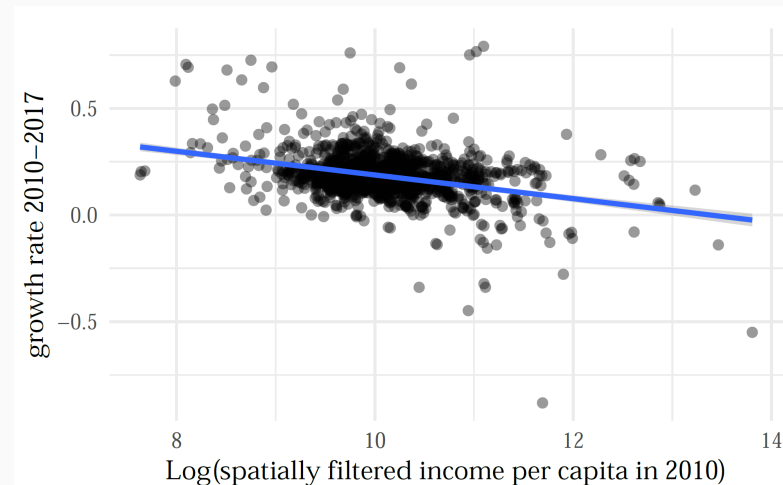

Table 1: Classical convergence framework summary

data (spatial scale)	speed of convergence	half-life(years)	quotient(σ)
RGDPpc(districts)	0.93***	74.2	1.03
RGDPpc(district-filtered)	1.14***	60.6	1.04*
RGDPpc(provinces)	1.44***	48.6	1.06

Note: unity. The speed of convergence is derived from a linear regression between the growth rate and the initial income value. *, **, *** indicate significance at the 10%, 5%, 1% levels respectively of the regression coefficient. For the quotients, the significance refers the difference from the null hypothesis of a quotient equal to 1.

(6) Concluding Remarks

Inequality still matters :

- Low mobility for the poorest districts and provinces.
- The convergence speed is below the standard in the regional literature for provinces.
- Spatial effects are reducing the pace of convergence at the district level.

Implications

- To spatially filter regional income is important in order to avoid misleading interpretations.
- Call for better coordination of regional policies at the cluster level.
- Enhance inter-regional connectivity and cooperation.
- Geography matters! breaking spatial barriers and the infrastructure and capabilities required for it must be on top of the policy agenda.

Thanks!

Thank you very much for your attention
